Report No. 97-15 March 1968

Abstract

The stability of a horizontal layer of fluid heated from below is examined when, in addition to a steady temperature difference between the walls of the layer, a time-dependent sinusoidal perturbation is applied to the wall temperatures. Only infinitesimal disturbances are considered. The effects of the oscillating temperature field are treated by a perturbation expansion in powers of the amplitude of the applied field. The shift in the critical Rayleigh number is calculated as a function of frequency, and it is found that it is possible to advance or delay the onset of convection by time modulation of the wall temperatures.

I. INTRODUCTION

R.J. Donnelly(1) has reported experiments on the effect of modulation on the stability of the flow between rotating cylinders. In his experiments, fluid was confined in the narrow gap between two cylinders, with the outer cylinder held fixed while the inner cylinder was given an angular speed $\Omega + \Delta\Omega \cos \omega t$. He found that the onset of instability was delayed by the modulation of the angular speed of the inner cylinder. Maximum stability was achieved for $\omega d^2/\nu \simeq 0.27$, and as the frequency was increased far beyond that point, the effect of modulation became negligible. Donnelly interpreted his results as being due to a viscous wave penetrating the fluid and thereby altering the profile from an unstable one to a stable one.

Since the problems of Taylor stability and Bénard stability are very similar, and the latter is simpler to analyze, this paper deals with the thermal analog of Donnelly's experiments. The problem considered is that of determining the onset of convection for a fluid layer heated from below, when in addition to a fixed temperature difference between the walls, an additional perturbation is applied to the wall temperatures, varying sinusoidally in time.

II. STATEMENT OF THE PROBLEM

The problem considered is the following. A fluid layer is confined between two infinite horizontal walls, a distance L apart. A vertical gravity force acts on the fluid. The wall temperatures are externally imposed, and they are

$$T_R + \frac{\Delta T}{2} \left[1 + \epsilon \cos \omega t \right] \tag{1}$$

at the lower wall $(z = 0)$, and

$$T_R - \frac{\Delta T}{2} [1 - \epsilon \cos(\omega t + \varphi)] \quad (2)$$

at the upper wall $(z = L)$. Here ϵ represents a small amplitude.

The fluid is supposed to be essentially incompressible, except insofar as its density changes due to thermal expansion. For small departures from a reference temperature T_R, the density is given by

$$\rho = \rho_R [1 - \alpha(T - T_R)] \quad (3)$$

where α is the coefficient of thermal expansion. The thermal diffusivity κ and the kinematic viscosity ν of the fluid will be regarded as constant, and the Boussinesq(2) approximation will be used to describe the motion of the fluid.

For simplicity, "free-free"(2) boundary conditions will be applied at the wall, instead of the more physical no-slip conditions. The free-free conditions are that the normal velocity is zero and the tangential stress is zero at the wall. They correspond to a rigid but slippery wall.

The object of the analysis is to determine the critical conditions under which convection can occur.

III. THE HYDROSTATIC CONFIGURATION

A hydrostatic configuration is possible for this system, in which the isothermal surfaces (and hence the isosteric surfaces) are horizontal and therefore parallel to the equipotential surfaces of the vertical gravitational force. Under such conditions a vertical pressure gradient can balance the gravitational force, and the fluid is subject to no net force. The equations which determine the temperature and pressure fields in this case are:

$$-\frac{\partial p_H}{\partial z} = \rho_H g \quad , \tag{4}$$

and

$$\frac{\partial T_H}{\partial t} = \kappa \frac{\partial^2 T_H}{\partial z^2} \quad . \tag{5}$$

Equations (3), (4) and (5) together with the boundary conditions (1) and (2) determined the hydrostatic fields $T_H(z,t)$, $\rho_H(z,t)$ and $p_H(z,t)$.

We shall only need the temperature field T_H, which, since Eq. (5) is linear, consists of the sum of a steady temperature field T_S and an oscillating part ϵT_1 :

$$T_H = T_S(z) + \epsilon\, T_1(z,t) \quad , \tag{6}$$

where

$$T_S = T_R + \Delta T(L - 2z)/2L \quad , \tag{7}$$

and

$$T_1 = \mathrm{Re}\{[\, a(\lambda)e^{\lambda z/L} + a(-\lambda)e^{-\lambda z/L}]\, e^{-i\omega t}\} \quad . \tag{8}$$

In Eq. (8),

$$\lambda = (1 - i)\left(\frac{\omega L^2}{2\kappa}\right)^{\frac{1}{2}} \quad , \tag{9}$$

and

$$a(\lambda) = \frac{\Delta T}{2}\; \frac{e^{-i\varphi} - e^{-\lambda}}{e^{\lambda} - e^{-\lambda}} \quad . \tag{10}$$

IV. EQUATIONS OF MOTION

In the Boussinesq approximation, the equations of motion are

$$\frac{\partial \underset{\sim}{v}}{\partial t} + \underset{\sim}{v}\cdot\nabla \underset{\sim}{v} + \frac{1}{\rho R}\nabla(p - p_H) = \nu\nabla^2 \underset{\sim}{v} + g\alpha(T - T_H)\underset{\sim}{k} \quad , \tag{11}$$

$$\nabla\cdot \underset{\sim}{v} = 0 \quad , \tag{12}$$

and

$$\frac{\partial T}{\partial t} + \utilde{v} \cdot \nabla T = \kappa \nabla^2 T \quad , \qquad (13)$$

where $\utilde{k}$ is the unit vector in the vertical direction, and $\utilde{v} = (u, v, w)$ is the fluid velocity.

Let

$$\theta = T - T_H \quad , \qquad (14)$$

then, retaining only linear terms in $\utilde{v}$ and θ, the equations of motion are

$$\frac{1}{\sigma} \frac{\partial \utilde{v}'}{\partial t'} + \nabla' p' = \nabla'^2 \utilde{v}' + R\theta' \utilde{k} \quad , \qquad (15)$$

$$\nabla' \cdot \utilde{v}' = 0 \quad , \qquad (16)$$

and

$$\frac{\partial \theta'}{\partial t'} + w' \frac{\partial T'_H}{\partial z'} = \nabla'^2 \theta' \quad . \qquad (17)$$

Here, the variables have been non-dimensionalized as follows:

$$\utilde{r}' = \utilde{r}/L \quad , \quad t' = \kappa t/L^2 \quad , \quad T' = T/\Delta T \quad ,$$

$$\utilde{v}' = \frac{L}{\kappa} \utilde{v} \quad , \quad p' = Lp/\rho_R \kappa^2 \quad .$$

The two dimensionless groups which appear are the Prandtl number, $\sigma = \nu/\kappa$, and the Rayleigh number, $R = g\alpha \Delta T L^3/\kappa \nu$.

From this point on we shall drop the primes, with the understanding that, unless otherwise stated, the quantities are in their non-dimensional form.

The boundary conditions at $z = 0$ and $z = 1$ are:

$w = 0$ (rigid wall),

$\dfrac{\partial^2 w}{\partial z^2} = 0$ (slippery walls), and

$$\theta = 0 \quad \text{(externally fixed temperature).}$$

We are interested in non-zero solutions to Eqs. (15) - (17) subject to these boundary conditions.

It is convenient to express the entire problem in terms of w. This is accomplished by taking the curl of Eq. (15) twice. The z component of the resulting equation involves only w and θ:

$$\left(\frac{1}{\sigma}\frac{\partial}{\partial t} - \nabla^2\right)\nabla^2 w = R\nabla_1^2\theta \quad , \tag{18}$$

where

$$\nabla_1^2 \equiv \partial^2/\partial x^2 + \partial^2/\partial y^2 \quad .$$

Equations (17) and (18) can then be combined to obtain

$$\left(\frac{1}{\sigma}\frac{\partial}{\partial t} - \nabla^2\right)\left(\frac{\partial}{\partial t} - \nabla^2\right)\nabla^2 w = -R\frac{\partial T_o}{\partial z}\nabla_1^2 w \quad . \tag{19}$$

The boundary conditions can also be expressed in terms of w by making use of Eq. (18), which requires $\partial^4 w/\partial z^4 = 0$ if w and θ are zero. Thus, Eq. (19) has to be solved subject to the homogeneous conditions

$$w = \partial^2 w/\partial z^2 = \partial^4 w/\partial z^4 = 0 \quad \text{at} \quad z = 0, 1 \quad . \tag{20}$$

The temperature gradient appearing in Eq. (19) can be obtained from the expressions derived in Section III:

$$\begin{aligned}\frac{\partial T_o}{\partial z} &= -1 + \epsilon\,\mathrm{Re}\{[A(\lambda)e^{\lambda z} + A(-\lambda)e^{-\lambda z}]e^{-i\omega t}\} \quad , \\ &= -1 + \epsilon f\end{aligned} \tag{21}$$

where

$$A(\lambda) = \frac{\lambda}{2} \frac{e^{-i\varphi} - e^{-\lambda}}{e^{\lambda} - e^{-\lambda}} \quad .$$

The horizontal dependence of w is factorable in this problem, and we shall study only solutions with a single wavenumber α, such that

$$\nabla_1^2 w = - \alpha^2 w \quad .$$

The dependence $e^{i\vec{\alpha}\cdot\vec{r}}$ of w on the horizontal coordinates is to be understood throughout, even though, for the sake of conciseness of notation the exponential factor will be left out.

V. PERTURBATION PROCEDURE

We seek the eigenfunctions w and eigenvalues R of Eqs. (19) and (20) for a temperature profile that departs from the linear profile $\partial T_0/\partial z = -1$ by quantities of order ϵ. It follows that the eigenfunctions and eigenvalues which obtain in this problem differ from those associated with the standard Benard problem by quantities of order ϵ. Accordingly, we seek an expansion of the form

$$\begin{aligned} w &= w_0 + \epsilon w_1 + \epsilon^2 w_2 + \ldots \\ R &= R_0 + \epsilon R_1 + \epsilon^2 R_2 + \ldots \quad . \end{aligned} \tag{22}$$

This type of expansion was first used in connection with convection problems by Malkus and Veronis(3) to consider effects of finite amplitude convection. More recently, a similar expansion was used by Schlüter, Lortz and Busse(4) to study the stability of finite amplitude convection, and by Ingersoll(5) to study the effect of superposing a shear flow, among others. This expansion is in effect a generalization of Rayleigh's perturbation procedure.

If the expansions (22) are substituted into Eq. (19) and the powers of ϵ are separated, the resulting system of equations is

$$
\begin{aligned}
L w_o &= 0 \\
L w_1 &= R_1 \nabla_1^2 w_o - R_{of} \nabla_1^2 w_o \quad , \\
L w_2 &= R_1 \nabla_1^2 w_1 + R_2 \nabla_1^2 w_o - R_c f \nabla_1^2 w_1 - R_1 f \nabla_1^2 w_o \quad , \\
&\quad \cdots
\end{aligned}
\tag{23}
$$

where

$$
L = \left(\frac{1}{\sigma} \frac{\partial}{\partial t} - \nabla^2 \right) \left(\frac{\partial}{\partial t} - \nabla^2 \right) \nabla^2 - R_o \nabla_1^2 \quad . \tag{24}
$$

Each of the w_n's is required to satisfy the boundary conditions (20).

The function w_o which starts the whole process is a solution of the problem with $\epsilon = 0$ that is, the classical Bénard problem. The marginally stable solutions for that problem are $^{(2)}$

$$
w_o^{(n)} = \sin n\pi z \quad ,
$$

with corresponding eigenvalues

$$
R_o^{(n)} = \frac{(n^2\pi^2 + \alpha^2)^3}{\alpha^2} \quad .
$$

For a fixed value of α the least eigenvalue is

$$
R_o = \frac{(\pi^2 + \alpha^2)^3}{\alpha^2} \quad , \tag{25}
$$

corresponding to

$$
w_o = \sin \pi z \quad . \tag{26}
$$

We shall use these as the starting point of our solution.

The equation for w_1 then reads

$$Lw_1 = -R_1\alpha^2 \sin \pi z + R_o\alpha^2 f \sin \pi z \quad . \tag{27}$$

If this equation is to have a solution, the right hand side must be orthogonal to the null space of the operator L. In effect, this solubility condition requires that the time independent part of the right hand side should be orthogonal to $\sin \pi z$. Since f varies sinusoidally in time, the only steady term is $-R_1\alpha^2 \sin \pi z$, so that R_1 is zero. Indeed, this could have been foreseen because R should be independent of the sign of ϵ, since changing the sign of ϵ merely corresponds to a shift in the time origin by half a period. Since such a shift does not change the problem of stability, it follows that all the odd coefficients $R_1, R_3 \ldots$ are zero.

Although Eq. (27) in principle can be solved in closed form, it is more convenient to expand the right hand side in a Fourier series, and thus obtain an expression for w_1 by inverting the operation L term by term. For this, the expansion of $e^{\lambda z}$ in a Fourier series is needed. For subsequent steps in the problem, we require the expansion of $e^{\lambda z} \sin m\pi z$. It is easily determined that

$$\begin{aligned} g_{nm}(\lambda) &= 2\int_0^1 e^{\lambda z} \sin n\pi z \sin m\pi z \, dz \quad , \\ &= -\frac{4nm\pi^2\lambda[1 + (-1)^{n+m+1}e^{\lambda}]}{[\lambda^2+(n+m)^2\pi^2][\lambda^2+(n-m)^2\pi^2]} \quad , \end{aligned} \tag{28}$$

so that

$$e^{\lambda z} \sin m\pi z = \sum_{n=1}^{\infty} g_{nm} \sin n\pi z \quad . \tag{29}$$

It is convenient to define

$$L(\omega, n) = \frac{\omega^2}{\sigma}(n^2\pi^2 + \alpha^2) + i\omega\left(1 + \frac{1}{\sigma}\right)(n^2\pi^2 + \alpha^2)^2 - (n^2\pi^2 + \alpha^2)^3 + (\pi^2 + \alpha^2)^3 \quad . \tag{30}$$

It follows that

$$L \sin n\pi z\, e^{-i\omega t} = L(\omega, n) \sin n\pi z\, e^{-i\omega t} \tag{31}$$

(with the horizontal dependence on $e^{i\underset{\sim}{\alpha}\cdot\underset{\sim}{r}}$ understood).

Equation (27) now reads

$$Lw_1 = R_0\alpha^2 \operatorname{Re}\left\{\sum [A(\lambda)g_{n_1}(\lambda) + A(-\lambda)g_{n_1}(-\lambda)]\, e^{-i\omega t}\sin n\pi z\right\} \quad ,$$

so that

$$w_1 = R_0\alpha^2 \operatorname{Re}\left\{\sum \frac{B_n(\lambda)}{L(\omega, n)}\, e^{-i\omega t}\sin n\pi z\right\} \quad , \tag{32}$$

where

$$B_n(\lambda) = A(\lambda)g_{n_1}(\lambda) + A(-\lambda)g_{n_1}(-\lambda) \quad . \tag{33}$$

A term proportional to $\sin \pi z$ (the solution to the homogeneous equation) could be added. However, this would merely amount to a renormalization of w, since all the terms proportional to $\sin \pi z$ could then be regrouped to define a new w_0, with corresponding new definitions for the other w_n's.

For this reason, it is convenient to assume from the outset that w_o is orthogonal to all the other w_n's.

The equation for w_2 is

$$Lw_2 = - R_2\alpha^2 w_o + R_o\alpha^2 f w_1 \quad . \tag{34}$$

We shall not require the solution of this equation, but merely use it to determine R_2, the first non-zero correction to R. The solubility condition requires that the steady part of the right hand side should be orthogonal to $\sin \pi z$, and therefore

$$R_2 = 2R_o \int_o^1 \overline{fw_1} \sin \pi z \, dz \quad , \tag{35}$$

where the bar denotes a time average.

Now, from Eq. (27)

$$f \sin \pi z = \frac{1}{\alpha^2 R_o} Lw_1 \quad ,$$

so that

$$\overline{fw_1} \sin \pi z = \frac{1}{\alpha^2 R_o} \overline{w_1 L w_1} \quad ,$$

$$= \alpha^2 \frac{R_o}{2} \operatorname{Re}\left\{ \sum \frac{B_n(\lambda)}{L(\omega, n)} \sin n\pi z \sum B_n^*(\lambda) \sin n\pi z \right\} \quad ,$$

and finally

$$R_2 = \alpha^2 \frac{R_o^2}{2} \operatorname{Re} \sum \frac{|B_n(\lambda)|^2}{L(\omega, n)} \quad ,$$

$$R_2 = \frac{\alpha^2 R_o^2}{4} \sum_{n=1}^{\infty} \frac{|B_n(\lambda)|^2}{|L(\omega, n)|^2} \left[L(\omega, n) + L^*(\omega, n) \right] \quad . \tag{36}$$

Equation (34) could now be solved for w_2 if desired, and the procedure continued to evaluate further corrections to w and R. However, we shall stop at this step.

VI. MINIMUM RAYLEIGH NUMBER FOR CONVECTION

The value of R obtained by this procedure is the eigenvalue corresponding to the function w which though oscillating, remains bounded in time. In general R is a function of the horizontal wavenumber α and the amplitude of the perturbation, ϵ. Thus

$$R(\alpha,\epsilon) = R_o(\alpha) + \epsilon^2 R_2(\alpha) + \ldots \quad . \tag{37}$$

As a function of α there will be a least value R_c of R at say $\alpha = \alpha_c$. This critical value of α occurs when $\partial R/\partial\alpha = 0$, that is when

$$\partial R_o/\partial\alpha_c + \epsilon^2\,\partial R_2/\partial\alpha_c + \ldots = 0 \quad . \tag{38}$$

Assume α_c is expanded in powers of ϵ,

$$\alpha_c = \alpha_o + \epsilon\alpha_1 + \epsilon^2\alpha_2 + \ldots \quad , \tag{39}$$

then Eq. (38) becomes

$$\partial R_o/\partial\alpha_o + \epsilon(\partial^2 R_o/\partial\alpha_o^2)\alpha_1 + \epsilon^2\Big[\tfrac{1}{2}(\partial^3 R_o/\partial\alpha_o^3)\alpha_1^2$$

$$+ (\partial^2 R_o/\partial\alpha_o^2)\alpha_2 + \partial R_2/\partial\alpha_o\Big] \ldots = 0 \quad ,$$

so that

$$\partial R_o/\partial\alpha_o = 0 \quad ,$$

$$\alpha_1 = 0 \quad ,$$

$$\alpha_2 = -(\partial R_2/\partial\alpha_o)/(\partial^2 R_o/\partial\alpha_o^2) \quad . \tag{40}$$

The first of these expressions gives $\alpha_o^2 = \pi/2$. A similar expansion obtains R_c:

$$\begin{aligned} R_c(\epsilon) &= R_{oc} + \epsilon^2 R_{2c} + \epsilon^4 R_{4c} + \dots \quad ; \\ &= R(\alpha_c, \epsilon) \quad , \\ &= R_o(\alpha_o) + \epsilon(\partial R_1/\partial\alpha_o)\alpha_1 + \epsilon^2\Big[\tfrac{1}{2}(\partial^2 R_o/\partial\alpha_o^2)\alpha_1^2 \\ &\qquad + (\partial R_o/\partial\alpha_o)\alpha_2 + R_2(\alpha_o)\Big] + \dots \\ &= R_o(\alpha_o) + \epsilon^2 R_2(\alpha_o) + \dots \end{aligned} \tag{41}$$

in view of Eqs. (40). Thus, to order ϵ^2, R_c is determined by evaluating R_o and R_2 at $\alpha = \alpha_o$. It is only when one reaches R_4 that α_2 must be taken into account. In the next section, the values of R_{2c} are found for three particular cases.

VII. RESULTS

The values of R_{2c} will be obtained for the following cases: (a) when the oscillating temperature field is symmetric i.e. the plate temperatures are modulated in phase, so $\varphi = 0$; (b) when the field is antisymmetric, corresponding to an out of phase modulation, $\varphi = \pi$; and (c) when only the temperature of the bottom plate is modulated, the upper plate being held at a fixed constant temperature. This case can be recovered from the equations by setting $\varphi = -i\infty$.(6)

In all three cases the expression for $B_n(\lambda)$ simplifies considerably. Let

$$b_n = -\frac{4\pi^2 n\lambda^2}{[\lambda^2 + (n+1)\pi^2][\lambda^2 + (n-1)^2\pi^2]} \quad , \tag{42}$$

then, for case (a)

$$B_n = b_n \quad \text{if} \quad n \quad \text{is even} \quad ,$$
$$= 0 \quad \text{if} \quad n \quad \text{is odd} \quad ;$$

for case (b)

$$B_n = 0 \quad \text{if} \quad n \quad \text{is even} \quad ,$$
$$= b_n \quad \text{if} \quad n \quad \text{is odd} \quad ;$$

and for case (c)

$$B_n = -\, b_n \quad \text{for all} \quad n, \quad \text{(see footnote 6).}$$

The variable λ was defined in Eq. (9), which in terms of the dimensionless frequency reduces to

$$\lambda = (1-i)(\omega/2)^{\frac{1}{2}} \quad ,$$

and thus

$$|b_n|^2 = \frac{16\pi^4 n^2 \omega^2}{[\omega^2 + (n+1)^4\pi^4]\,[\omega^2 + (n-1)^4\pi^4]} \quad . \tag{43}$$

We also need an expression for

$$C_n = [\, L(\omega, n) + L^*(\omega, n)] / 2\,|L(\omega, n)|^2$$

evaluated at $\alpha^2 = \pi/2$. This reduces to

$$C_n = \frac{\frac{\omega^2}{\sigma}(n^2+1/2)\pi^2 - (n^2+1/2)^3\pi^6 + \frac{27\pi^6}{8}}{\left[\frac{\omega^2}{\sigma}(n^2+1/2)\pi^2 - (n^2+1/2)^3\pi^6 + \frac{27\pi^6}{8}\right]^2 + \omega^2\left(1+\frac{1}{\sigma}\right)^2(n^2+1/2)^4\pi^8} \quad , \tag{44}$$

and finally

$$R_{2c} = \frac{729}{64}\,\pi^{10} \sum |b_n|^2 C_n \quad , \tag{45}$$

where the sum extends over even values of n for case (a), odd values for case (b) and all values for case (c). The series defined by Eq. (45) converges rapidly since the terms decrease like $1/n^{12}$.

Numerical results of R_{2c} as a function of ω for various values of σ are exhibited in the accompanying figures.

VIII. DISCUSSION

Some features of the behavior of R_{2c} as a function of ω can be seen by examining the limiting cases for very small or very large values of ω. When ω is very small,

$$C_1 |b_1|^2 \rightarrow 1/[\,3\sigma(1 + 1/\sigma)^2\pi^6/2] \quad ,$$

while for $n \neq 1$

$$C_n |b_n|^2 \rightarrow - \frac{16\, n^2\omega^2}{(n^2-1)^5 (n^4 + \frac{5}{2} n^2 + \frac{13}{4})\pi^{10}} \quad ,$$

so the general form of R_{2c} near $\omega = 0$ is

$$R_{2c} \rightarrow R_\sigma - \beta\omega^2 \quad ,$$

where

$$R_\sigma = 27\pi^4/8\sigma(1+1/\sigma)^2 \quad , \qquad (46)$$

and β is a constant, which depends only on the case being considered.

In the case of symmetric excitation, the sum extends only over even values, so that

$$R_{2c} \rightarrow - 0.102\,\omega^2 \quad ,$$

indicating that the dependence on σ can only appear at reasonably large values of ω. The effect of modulation in this case is to destabilize the system, with convection occurring at an earlier point than in the unmodulated system. This agrees with the results of Krishnamurti(7) in her analysis of convection with a slowly varying mean temperature, which corresponds to low frequency symmetric excitation.

In the antisymmetric case

$$R_{2c} \to R_\sigma - 0.0005\omega^2 \quad ,$$

so the effect is one of stabilization, decreasing with frequency. The maximum value of R_σ obtains at $\sigma = 1$ and is 82.1. Since R_{oc} is only eight times as large, there is a good chance that this effect can be observed experimentally, for a moderately large amplitude of modulation, assuming that, at least qualitatively, these results can be extrapolated to ϵ near 1.

The value of R_{2c} for the case in which only the bottom temperature is modulated is obtained by adding the other two, so that

$$R_{2c} \to R_\sigma - 0.103\omega^2 \quad .$$

For σ near 1, this is not significantly different from case (b); however for larger σ, R_σ can become sufficiently small to be overtake by the other terms in the sum.

As ω tends to infinity, R_{2c} tends to zero as $1/\omega^2$, so the effect of modulation disappears altogether. This agrees with Donnelly's experiments on the stability of Taylor vortices. For intermediate values of ω, the effect of changing the frequency makes itself evident in the numerator of C_n. If ω^2/σ is as large as $(n^2 + 1/2)^2\pi^4$ C_n is positive rather than negative. Indeed, C_2 is zero when

$$\omega = \pi^2 (78\sigma)^{\frac{1}{2}} / 2 \quad , \tag{47}$$

so that in the symmetric case R_{2c} should be zero near that value of ω, a prediction which is borne out by the numerical calculations. Thus, for example, for $\sigma = 10$, Eq. (47) gives $\omega = 138$ while from the numerical results, R_{2c} is zero at $\omega = 145$. The peak negative value of R_{2c} is more difficult to estimate, but appears from the numerical evaluation of the series that it occurs near $\omega = 20$ and has a value of about -6, over the entire range of σ.

None of the cases considered duplicates the behavior observed by Donnelly in his experiments, in which a peak stabilization occurs at a value of ω different from zero. This is probably due to the fact that while the two problems are fairly similar, they are not identical.

IX. ACKNOWLEDGMENTS

The author is grateful to Professor A. Ingersoll, for his valuable advice and interest in this study.

13. ABSTRACT

The stability of a horizontal layer of fluid heated from below is examined when, in addition to a steady temperature difference between the walls of the layer, a time-dependent sinusoidal perturbation is applied to the wall temperatures. Only infinitesimal disturbances are considered. The effects of the oscillating temperature field are treated by a perturbation expansion in powers of the amplitude of the applied field. The shift in the critical Rayleigh number is calculated as a function of frequency, and it is found that it is possible to advance or delay the onset of convection by time modulation of the wall temperatures.

INSTRUCTIONS

1. ORIGINATING ACTIVITY: Enter the name and address of the contractor, subcontractor, grantee, Department of Defense activity or other organization *(corporate author)* issuing the report.

2*a*. REPORT SECURITY CLASSIFICATION: Enter the overall security classification of the report. Indicate whether "Restricted Data" is included. Marking is to be in accordance with appropriate security regulations.

2*b*. GROUP: Automatic downgrading is specified in DoD Directive 5200.10 and Armed Forces Industrial Manual. Enter the group number. Also, when applicable, show that optional markings have been used for Group 3 and Group 4 as authorized.

3. REPORT TITLE: Enter the complete report title in all capital letters. Titles in all cases should be unclassified. If a meaningful title cannot be selected without classification, show title classification in all capitals in parenthesis immediately following the title.

4. DESCRIPTIVE NOTES: If appropriate, enter the type of report, e.g., interim, progress, summary, annual, or final. Give the inclusive dates when a specific reporting period is covered.

5. AUTHOR(S): Enter the name(s) of author(s) as shown on or in the report. Enter last name, first name, middle initial. If military, show rank and branch of service. The name of the principal author is an absolute minimum requirement.

6. REPORT DATE: Enter the date of the report as day, month, year; or month, year. If more than one date appears on the report, use date of publication.

7*a*. TOTAL NUMBER OF PAGES: The total page count should follow normal pagination procedures, i.e., enter the number of pages containing information.

7*b*. NUMBER OF REFERENCES: Enter the total number of references cited in the report.

8*a*. CONTRACT OR GRANT NUMBER: If appropriate, enter the applicable number of the contract or grant under which the report was written.

8*b*, 8*c*, & 8*d*. PROJECT NUMBER: Enter the appropriate military department identification, such as project number, subproject number, system numbers, task number, etc.

9*a*. ORIGINATOR'S REPORT NUMBER(S): Enter the official report number by which the document will be identified and controlled by the originating activity. This number must be unique to this report.

9*b*. OTHER REPORT NUMBER(S): If the report has been assigned any other report numbers *(either by the originator or by the sponsor)*, also enter this number(s).

10. AVAILABILITY/LIMITATION NOTICES: Enter any limitations on further dissemination of the report, other than those imposed by security classification, using standard statements such as:

(1) "Qualified requesters may obtain copies of this report from DDC."

(2) "Foreign announcement and dissemination of this report by DDC is not authorized."

(3) "U. S. Government agencies may obtain copies of this report directly from DDC. Other qualified DDC users shall request through
____."

(4) "U. S. military agencies may obtain copies of this report directly from DDC. Other qualified users shall request through
____."

(5) "All distribution of this report is controlled. Qualified DDC users shall request through
____."

If the report has been furnished to the Office of Technical Services, Department of Commerce, for sale to the public, indicate this fact and enter the price, if known.

11. SUPPLEMENTARY NOTES: Use for additional explanatory notes.

12. SPONSORING MILITARY ACTIVITY: Enter the name of the departmental project office or laboratory sponsoring *(paying for)* the research and development. Include address.

13. ABSTRACT: Enter an abstract giving a brief and factual summary of the document indicative of the report, even though it may also appear elsewhere in the body of the technical report. If additional space is required, a continuation sheet shall be attached.

It is highly desirable that the abstract of classified reports be unclassified. Each paragraph of the abstract shall end with an indication of the military security classification of the information in the paragraph, represented as *(TS)*, *(S)*, *(C)*, *or (U)*.

There is no limitation on the length of the abstract. However, the suggested length is from 150 to 225 words.

14. KEY WORDS: Key words are technically meaningful terms or short phrases that characterize a report and may be used as index entries for cataloging the report. Key words must be selected so that no security classification is required. Identifiers, such as equipment model designation, trade name, military project code name, geographic location, may be used as key words but will be followed by an indication of technical context. The assignment of links, roles, and weights is optional.
